We can approach hypothesis testing for  $\bar{x}$  in mostly the same way that we approached  $\hat{p}$ . However,

- We will often run into situations where  $\bar{x}$  is not approximately normal.
- We will develop a framework for dealing with these situations.

When we collect a sufficiently large sample of n independent observations from a population with mean  $\mu$  and standard deviation  $\sigma$ , the sampling distribution of  $\bar{x}$  will be nearly normal with mean

and standard error

 $\mu$ 

-

San

イロト イヨト イヨト --

For the Central Limit Theorem to hold, we require

- Independence
- Normality

< 注→ 注

DQC

For  $\bar{x}$  to be normally distributed,

- We require that the observations x used to calculate  $\bar{x}$  be from a normally distributed population.
- When this doesn't hold, we require a large sample size.

I D F I A B F I B F

三 ) (

3

San

So what is a "large sample size"?

n < 30: A sample size *n* less than 30 is considered a small sample. In this case, we will need the data to come from a nearly normal distribution.

 $n \geq 30$ : A sample side *n* of at least 30 is considered a large sample. Then we can assume that  $\bar{x}$  is nearly normal.

In both cases, we need to be wary of outliers as these can cause problems with our results.

200

<ロト (四) (三) (三) (三) (三)

Are the independence and normality conditions met in each case?

Section 7.1

August 26, 2019

≣⇒

< D > < D

æ

DQC

Are the independence and normality conditions met in each case?

For the first plot, n = 15 and there are no clear outliers. For the mean to be normally distributed, we would have to justify that these are draws from a normal distribution.

æ

Are the independence and normality conditions met in each case?

For the second plot, n = 50 but there is an extreme outlier at about 22. This outlier will prevent us from confidently using a normal distribution.

< □ > < / >

코 🕨 🛛 코

We will start with the situation wherein we know that  $X \sim N(\mu, \sigma)$ and the value of  $\sigma$  is known. This  $(1 - \alpha)100\%$  confidence interval for  $\mu$  is

$$\bar{x} \pm z_{\alpha/2} imes rac{\sigma}{\sqrt{n}}$$

where  $\sigma/\sqrt{n}$  is the SE and  $z_{\alpha/2}$  is again the critical value.

The following n = 5 observations are from a  $N(\mu, 2)$  distribution. Find a 90% confidence interval for  $\mu$ .

So we can be 90% confident that the true mean  $\mu$  is in the interval (0.1687, 3.1113).

590

Recall that when we say "90% confident", we mean:

• If we draw repeated samples of size 5 from this distribution, then 90% of the time the corresponding intervals will contain the true value of  $\mu$ .

DQC

- In practice, we typically do not know the population standard deviation  $\sigma$ .
- Instead, we have to estimate this quantity.
- We will use the sample statistic s to estimate  $\sigma$ .
- This strategy works quite well when  $n \ge 30$

San

<ロト (四) (三) (三) (三) (三)

This works quite well because we expect large samples to give us precise estimates such that

$$SE = \frac{\sigma}{\sqrt{n}} \approx \frac{s}{\sqrt{n}}.$$

When  $n \ge 30$  and  $\sigma$  is unknown, a  $(1 - \alpha)100\%$  confidence interval for  $\mu$  is

$$\bar{x} \pm z_{\alpha/2} \frac{s}{\sqrt{n}}$$

where we've plugged in s for  $\sigma$ .

The average heart rate of a random sample of 60 students is found to be 74 with a standard deviation of 11. Find a 95% confidence interval for the true mean heart rate of the students.

Sample size calculation for means is essentially the same as for proportions!

$$n \ge \left(\frac{z_{\alpha/2} \times sd}{MoE}\right)^2$$

Section 7.1

August 26, 2019

A manufacturer claims with 95% confidence that his product is accurate within 0.2 units with a standard deviation of 0.2626. What sample size would we need to demonstrate this claim? We begin with the setting where  $n \ge 30$ .

- As before, it is possible to use the confidence interval to complete a hypothesis test.
- However, we also want to be able to use our test statistic and p-value approaches.

- 12

San

イロト イポト イヨト イヨト

For  $n \geq 30$ , the test statistic is

$$ts = z = \frac{\bar{x} - \mu_0}{s/\sqrt{n}}$$

where again  $s/\sqrt{n} \approx \sigma/\sqrt{n}$  because we are using a large sample.

There are five steps to carrying out these hypothesis tests:

- Write out the null and alternative hypotheses.
- **2** Calculate the test statistic.
- **③** Use the significance level to find the critical value

#### OR

use the test statistic to find the p-value.

Ompare the critical value to the test statistic

#### OR

compare the p-value to  $\alpha$ .

• Conclusion.

3

Sar

In its native habitat, the average density of giant hogweed is 5 plants per  $m^2$ . In an invaded area, a sample of 50 plants produced an average of 11.17 plants per  $m^2$  with a standard deviation of 8.9. Does the invaded area have a different average density than the native area? Test at the 5% level of significance.

San

イロト 不同下 不良下 不良下 一日

We now move to the situation where n < 30.

If n < 30 but we are dealing with a normal distribution and  $\sigma$  is known,

$$ts = z = \frac{\bar{x} - \mu_0}{\sigma / \sqrt{n}}$$

but we know that this will rarely (if ever) occur in practice!

- With a small sample size, plugging in s for  $\sigma$  can result in some problems.
- Therefore less precise samples will require us to make some changes.
- This brings us to the *t*-distribution.

San

The t-distribution is a symmetric, bell-shaped curve like the normal distribution.

However, the *t*-distribution has more area in the tails.

28 / 36

## Introducing the t-Distribution

These thicker tails turn out to be exactly the correction we need in order to use s in place of  $\sigma$  when calculating standard error!

The t-distribution:

- Is always centered at zero.
- Has one parameter: degrees of freedom (df).
- For our purposes,

$$df = n - 1$$

where n is our sample size.

<ロト <回ト < 回ト < 三ト

3

- For the *t*-distribution, the parameter df controls how fat the tails are.
- Higher values of df result in thinner tails.
  - That is, higher df results in a t-distribution that looks more like a normal distribution.
  - $\bullet\,$  I.e., bigger sample sizes make the t-distribution look more normal.
- When  $n \ge 30$ , the *t*-distribution will be essentially equivalent to the normal distribution.

- 12

Sar

(日) (종) (종) (종)

When n < 30 and  $\sigma$  is unknown, we use the *t*-distribution for our confidence intervals. A  $(1 - \alpha)100\%$  confidence interval for  $\mu$  is

$$\bar{x} \pm t_{\alpha/2,df} imes rac{s}{\sqrt{n}}$$

Section 7.1

August 26, 2019

32 / 36

(日) (종) (종) (종)

ъ

Let's take a minute to look at the table of *t*-distribution critical values that will be provided for your final exam.

<ロト <回ト < 回ト < 三ト

∃ <\0<</p>

The test statistic for the setting where n < 30 and  $\sigma$  is unknown is

$$ts = t = \frac{\bar{x} - \mu_0}{s/\sqrt{n}}$$

(two-sided hypotheses)

臣

DQC

(日) (四) (日) (日) (日)

### The p-value for the two-sided hypotheses is then

$$2 \times P(t_{df} < -|ts|)$$

Section 7.1

August 26, 2019

The following data is on red blood cell counts (in  $10^6$  cells per microliter) for 9 people:

5.4, 5.3, 5.3, 5.2, 5.4, 4.9, 5.0, 5.2, 5.4

Test at the 5% level of significance if the average cell count is 5.
